ABSTRACT

1 Introduction

Cadmium sulfide (CdS) is in the class II-VI semiconductor.

In 2.1 Chap 1 we will use the free elecon model to obtain some results for a given metal and discribe some of the basic concepts. In the model metals are

In 2.2 Chap 2 *Elementary Solid State Physics* [1] delivered insights in these concepts to get

In 2.3 Chap 3 we will show some of these effects.

2 Results

2.1 Chap 1

Question 1

$$\sigma = \frac{Ne^2\tau}{m^*} \tag{1}$$

At it is a monovalent metal and the FCC-Unit cell contains 4 atoms the concentration of the conduction electrons N can be calculated as:

$$N = \frac{4}{a^3}$$

So for the collision time τ follows: With $(m^* = m_0)$ the free electron mass.

The electrical resitivity is given as: $\rho = 2.13\mu\Omega cm$

which leads to a conducitivity of $\sigma = \frac{1}{\rho} = 4.695 \cdot 10^7 \frac{1}{\Omega m}$

$a = 5.82\AA$

$$\tau = \frac{\sigma \cdot m^* \cdot a^3}{4e^2} = 28.5 \cdot 10^{-14} s$$

Question 2

For a thin metal wire with a length of $10\,cm$, a square cross section with a side of $0.1\,mm$ and a potential difference along the wire of $0.2\,V$

The electric field E in the wire can be calculated as:

$$E = \frac{U}{L} = 2\frac{V}{m}$$

As for the current density the following relations are known.

$$J = \sigma E \qquad J = nev_D$$

So for the drift velocitiy follows:

$$v_D = \frac{\sigma E}{ne}$$

Fermi

The energy of the electron in a metal is quantized according to quantum mechanics. As so they follow the *Pauli exclusiion principle*, which means only two electrons with diffenrent spin can occupy one energy level. The highest occupied energy level is then called the Fermi energy or the fermy level.

The situation described obtains in metals as $T = 0°K$. The probability that an level below the fermi energy is occupied is 1 and above equals 0.

If the system is heated,

Which leads to the *Fermi-Dirac distribution*

$$f(E) = \frac{1}{e^{(E-E_F)/kT} + 1} \tag{2}$$

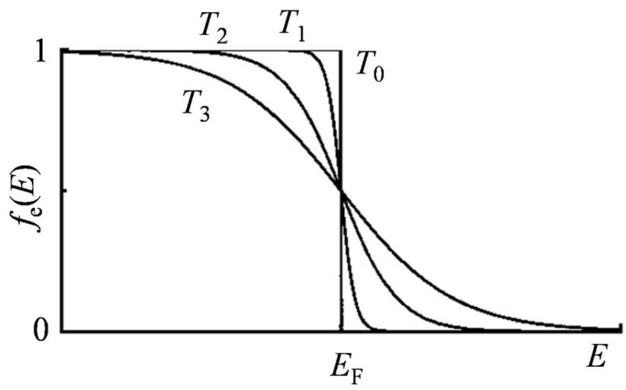

Figure 1: Fermi-Dirac distribution function at different temperatures: T3> T2>T1 (and T0 = 0 K). At the absolute zero temperature (T0), the probability of an electron to have an energy below the Fermi energy EF is equal to 1, while the probability to have higher energy is zero.

As the energy of an electron is entirely kinetic, it is possible to write the energy as:

$$E = \frac{1}{2} m^* v^2$$

As for the $T = 0°$ the fermi energy is the highest possible value a maximum velocitiy v_F of the particles can be found.

$$E_F = m^* v_F^2$$

This leads to a shere in the three dimesional velocitiy space (v_x, v_y, v_z) the sphere has an radius of v_F

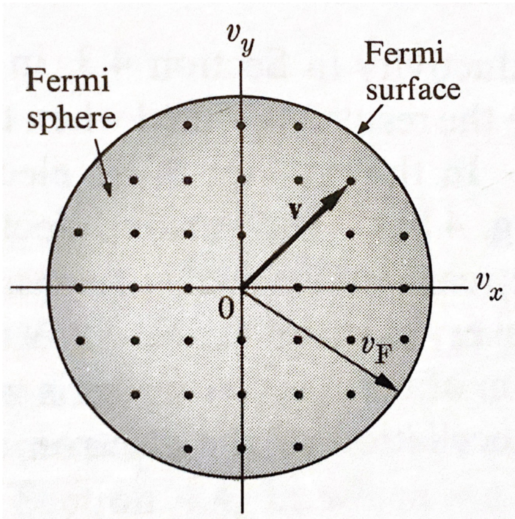

Figure 2: The Fermi surface and the Fermi sphere [1, asdfadf]

Cyclotron

$$-e(\vec{v} \times \vec{B}) = m\frac{d\vec{v}}{dt} \tag{3}$$

With the given information that $\vec{B} = B\vec{z}$ The equation above lead to the following:

$-ev_yB = m\frac{d}{dt}v_x$
$ev_xB = m\frac{d}{dt}v_y$

Which can be solved with the additional information

$$x = k_{0x}$$

$$\omega = \frac{eB}{m^*}$$

Plasma Frequency

$$w_P = \frac{Ne^2}{\epsilon_L m^*} \tag{4}$$

2.2 Chap 2

2.3 Chap 3

Question 1

The carrier distribution function in CB für an intrinsic semiconductor is given as the product:

$$g_e(E)f(E)$$

with

$$g_e(E) = \frac{1}{2\pi^2}\left(\frac{2m_e^*}{\hbar}\right)^{\frac{3}{2}}(E-E_C)^{\frac{1}{2}}$$

$$f(E) = \frac{1}{e^{(E-E_F)/k_BT}+1} \approx e^{-\frac{E-E_F}{k_BT}}$$

So for the maximum

$$\frac{d}{dE}\left(\frac{1}{2\pi^2}\left(\frac{2m_e^*}{\hbar}\right)^{\frac{3}{2}}(E-E_C)^{\frac{1}{2}}e^{-\frac{E-E_F}{k_BT}}\right) = 0$$

By dividing through the constant factors:

$$\frac{d}{dE}\left((E-E_C)^{\frac{1}{2}}e^{-\frac{E}{k_BT}}\right) = 0$$

$$\frac{1}{2}(E-E_C)^{-\frac{1}{2}}e^{-\frac{E}{k_BT}} + \frac{-1}{k_BT}(E-E_C)^{\frac{1}{2}}e^{-\frac{E}{k_BT}} = 0$$

And finaly

$$E = E_C + \frac{k_BT}{2}$$

Question 2

$$N_c = 2\left(\frac{m_e^*k_BT}{2\pi\hbar^2}\right)^{\frac{3}{2}}$$

$$N_c = 2.415\cdot 10^{24}\frac{1}{m^3}$$

$$N_v = 2\left(\frac{m_h^*k_BT}{2\pi\hbar^2}\right)^{\frac{3}{2}}$$

$$N_v = 1.796 \cdot 10^{25} \frac{1}{m^3}$$

$$n_i = p_i = 2 \left(\frac{k_B T}{2\pi\hbar^2} \right)^{\frac{3}{2}} (m_e^* m_h^*)^{\frac{3}{4}} e^{-\frac{E_g}{2k_B T}}$$

$$n_i = p_i = 0.959 \cdot 10^3 \frac{1}{m^3}$$

$$E_{Fi} = \frac{E_g}{2} + \frac{3}{4} k_B T \ln \left(\frac{m_h^*}{m_e^*} \right)$$

$$E_{Fi} = 1.326 eV$$

Question 3

If the given semiconductor CdS was doped p-type with a concentration of 10^{15} acceptor impurities the following about the concentration and holes at $T = 0°K$ can be said.

At this point the thermal energy becomes too small to cause electron exication, which means that all electrons fall from the conducition Band into the donor level. Also the conductivity goes to zero. This process is called freeze out. So for the concentration of electron and holes at $T = 0°K$

The concentration of the elctrons:

$n(T = 0°K) = 0$

As the semiconductor is doped with holes the concentration of the holes is the same as it was initaly.

$p(T = 0°K) = 10^{15} cm^{-3}$

Question 4

$p = 10^{15} \frac{1}{cm^3} = 10^{18} \frac{1}{m^3} \qquad \gg p_i$

As the square of the intrinsic concentrationnn_i is equal to the product of the sum of the concentration of the holes and the concentration of the electrons.

$$np = n_i^2$$

$$n = \frac{n_i^2}{p} = \frac{(0.959 \cdot 10^3 \frac{1}{m^3})^2}{10^{18} \frac{1}{m^3}} = 9.197 \cdot 10^{-13} \frac{1}{m^3}$$

$$n = n_i e^{\frac{E_F - E_{Fi}}{k_B T}} \qquad p = n_i e^{-\frac{E_F - E_{Fi}}{k_B T}}$$

$$(E_F - E_{Fi}) = \ln\left(\frac{n}{n_i}\right) \cdot k_B T$$

$$(E_F - E_{Fi}) = -0.896 eV$$

Question 5

$$\epsilon_r = 8.9$$

$$E_a = \frac{1}{\epsilon_r^2}\left(\frac{m_h}{m_0}\right)\underbrace{\left[\frac{e^4 m_0}{2(4\pi\epsilon_h \hbar)^2}\right]}_{13.6 eV}$$

$$E_a = 0.14 eV$$

Question 6

Question 7

3 Conclusion

This report

For a given monovalent metal which crystals in the FFC structure with a unit cell size of $a = 4.09\AA$ the the collistion time could be calculated as:

$$\tau = 28.5 \cdot 10^{-14} s$$

The value of the intrinsic fermi level for CdS was found to be

$$E_{Fi} = 1.326 eV$$
